# 1 Project Summary

Partridge is a web-based tool designed to assist in information processing and knowledge acquisition within the domain of scientific research.

Since the advent of the 'Digital Age' and the ability of computers to copy and reproduce information for a negligible cost, the amount of information available to researchers has been increasing drastically. A 2009 study by B-C Björk suggests that approximately 1.4 Million papers were published in the year 2006 alone[2]. Moreover, the growing popularity of Open Access publishing (making papers available for free online[7]) across most scientific disciplines[2][3] is providing researchers with an even larger volume of information to be processed. As available information increases, relevant material becomes progressively more difficult to find and the need for an automated information retrieval tool more apparent.

Partridge aims to autonomously process as many scientific papers as possible to facilitate researchers who would otherwise be required to manually read each paper themselves. This should reduce the amount of information that the reader is required to process themselves, thereby speeding up the research process. Partridge will achieve this through the use of several existing techniques in the field of Natural Language Processing which are discussed below.

From the point of view of it's users, Partridge will assist researchers in two ways. The system will provide filtering of papers based upon their specific domain (i.e. is the paper primarily concerned with methodology within an experiment in chemistry or is it about Ethics in Psychological studies?) and their result, whether the paper yielded positive, negative or inconclusive evidence for a hypothesis. Depending upon the time constraints of the project, it is hoped that Partridge will also offer a user 'profiling' system that provides recommendations for researchers based on their reading history. This feature should help users find relevant papers more quickly or find research that they may have otherwise overlooked.

There are already several tools that help researchers manage the vast library of internet journals available on the internet. Search engines such as Google (<http://www.google.com/>), and social citation management tools such as CiteULike (<http://www.citeulike.org>), do offer some assistance in tracking down relevant information. However, these tools are often too general or rely upon the user knowing exactly what keywords to search for before carrying out the search. These drawbacks are further discussed in Section 2.1 below.

To overcome the drawbacks of these existing systems, Partridge will make use of several modern Natural Language Processing (NLP) techniques. NLP enables the automated extraction of meaningful information from texts written in human languages such as English or French. There have already been several papers on using NLP for detecting emotions in suicide notes[4], the genre of a web page on the World Wide Web[6] and emotional polarity of a phrase or sentence[8]. Liakata et al. have also used NLP techniques to classify sentences within scientific papers to determine what scientific concept they relate to (i.e. does this sentence cover background information or is it a part of the

hypothesis?)[5]. Partridge will build upon and make use of these existing applications of NLP to filter and retrieve data from scientific papers in a novel way.

## 2 Current Progress

The Partridge project has been underway since the beginning of October. The following section looks at related works and how Partridge compares to them, some prior investigation and prototyping work that has already been carried out.

### 2.1 Related Works

There are already many existing systems for finding and filtering information on the World Wide Web. Search engines are very useful for information retrieval in this very large and generalised search domain. Most people have heard of Google (<http://www.google.com>), Yahoo (<http://www.yahoo.co.uk>), Bing (<http://www.bing.com>) and Ask (<http://www.ask.com>). There are many more similar systems available for free general use across the internet. They all present very similar user interfaces (as shown in Figure 1) in which users are asked to supply keywords that might be linked to relevant documents and the search engine returns a list of Uniform Resource Locators (URLs) that they consider to match the user's query.

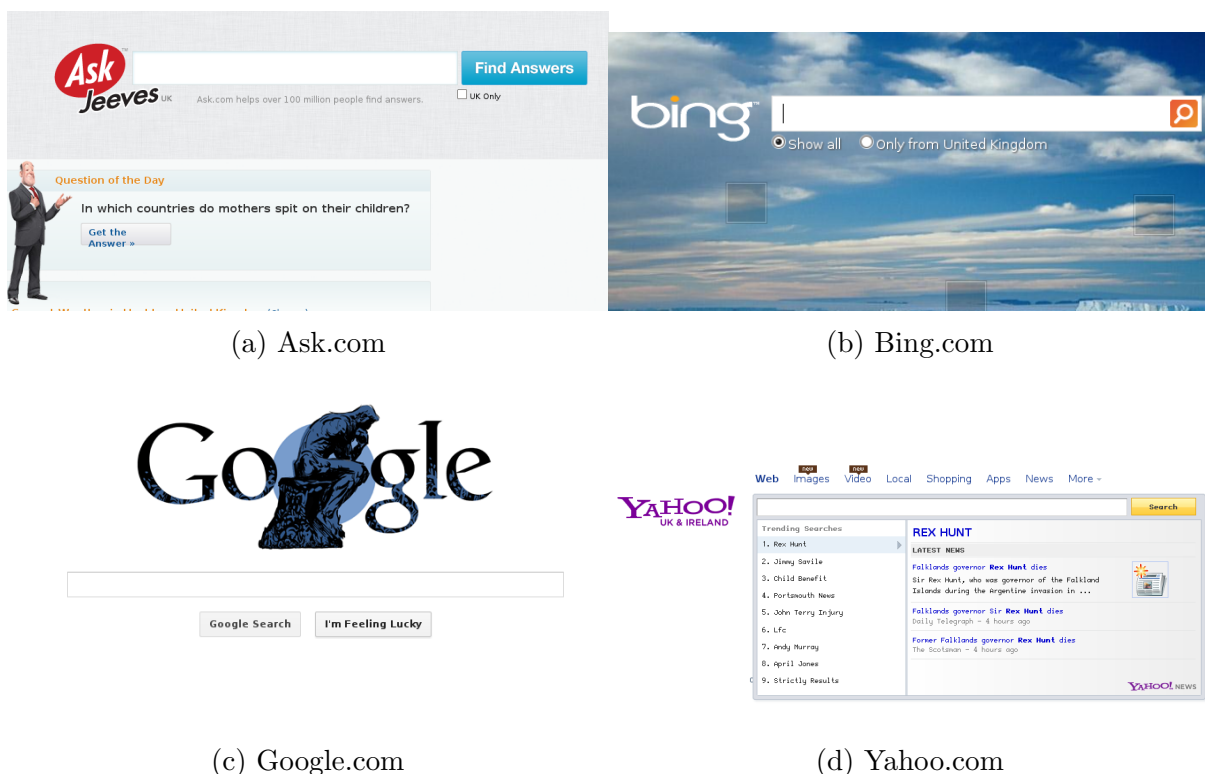

Figure 1: 4 popular search engine interfaces

Search engines are helpful in locating pages and websites within the World Wide Web. Unfortunately, the problem space they deal with is usually too big for them to find scientific papers and journals given a set of keywords. Internet search engines index a huge proportion of irrelevant information compared to useful information[1], and as a result, even relatively specific queries such as effects of gravity on rockets” yield millions of results (as shown in Figure 2).

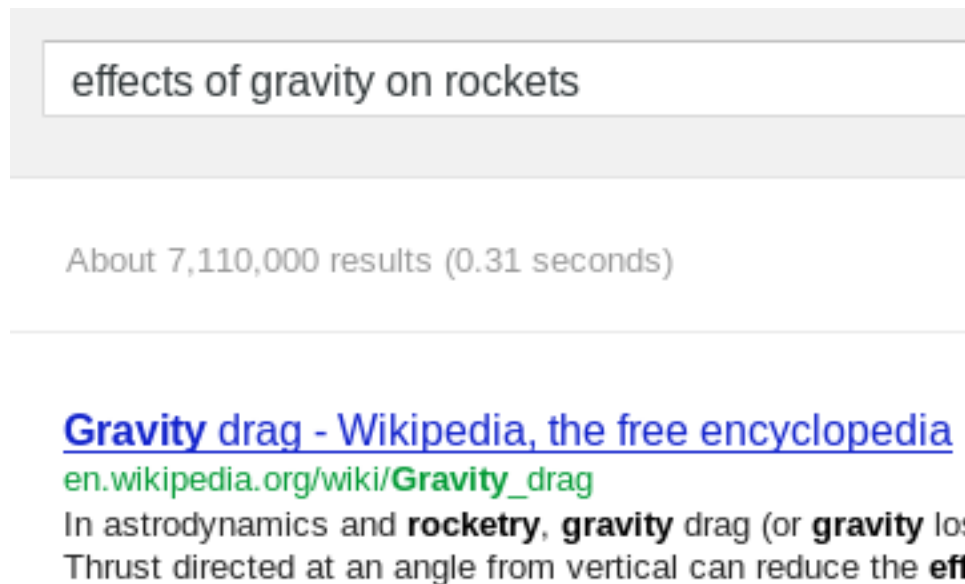

Figure 2: Google showing over 7M results for “effects of gravity on rockets”

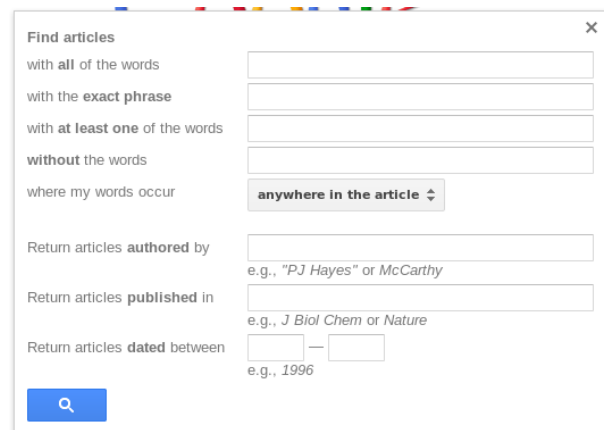

Partridge offers an advantage over these mechanisms as it will specifically index research papers rather than attempting to index the whole Internet. This means that there should be a higher proportion of useful information as output compared to the output of an Internet Search Engine.

There are also a number of search and indexing systems that specifically look for scientific papers as opposed to web pages. One of the most publicised and well known paper search system is Google Scholar (Figure 3). This is an adaptation of Google’s general search engine (discussed above) to specifically index and search scientific papers. Google also offers advanced query options specific to Scholar that allow searching by author, year and for words that occur only in the document title. Whilst this does deal with the problem of ‘information overload’ and provides even more fine control over the information returned from searches, the user is still required to have a very good idea of what they are looking for in terms of keywords and/or specific authors. It is possible that a user would not know what they are looking for until they’ve seen it.

Partridge will provide the option to filter papers by subject and it is hoped that the system will also provide user-specific recommendations by profiling them through their reading history. This will make it easier for users to find relevant papers without knowing exactly what keywords they want to search for.
